1 Resolution tests

We conducted checkerboard resolution tests to confirm the reliability of the obtained tomographic images. To make a checkerboard, we assigned alternative positive and negative velocity anomalies of 6% to all the 3-D grid nodes. Random errors with a standard deviation of 0.1 s were added to the synthetic arrival times calculated for the checkerboard model to account for the picking errors existing in the real data.

Figs. S1 and S2 show the finite-frequency results of the checkerboard tests at four layers in the crust under the area where the 2011 Iwaki earthquake occurred and the Fukushima nuclear power plant (FNPP) is located for the Vp and Vs structures, while Figs. S3 and S4 show the finite-frequency results at four layers in the upper mantle beneath the whole study area. The corresponding test results with the ray tomography method (Zhao et al., 1992) are demonstrated in Figs. S5-S8. Although the resolution is lower at 12.0 km depth, the results of resolution tests indicate that the two tomographic methods can well resolve
the heterogeneities in the Iwaki earthquake and FNPP area. To further demonstrate the recovery ability of the tomographic methods, we adopted the structural similarity (SSIM) index (Tong et al., 2011) to quantitatively measure the recovery rate of synthetic test with respect to the checkerboard model. For both the finite-frequency and ray tomography methods, Table S1 shows the SSIM indices between the input checkerboard model and the inversion results at different depths. Each index in this table corresponds to one subfigure in Figs. S1-S8. The SSIM indices indicate that the data set used in this study guarantees satisfactory recovery rates for both tomographic methods.

2 Ray and finite-frequency tomographic images

The finite-frequency results of the crustal Vp and Vs structures at four representative layers in the Iwaki earthquake and FNPP area are shown in Figs. S9 and S10. The corresponding results of ray tomography are demonstrated in Figs. S11 and S12. Strong lateral heterogeneities are revealed in the study area (Figs. S9-S12). The 2011 Iwaki mainshock (M 7.0) and its large aftershocks (M > 5.0) are located in a boundary zone with strong variations in seismic velocities. Low-velocity (low-V) anomalies are noticeable in the upper crust in and around FNPP.

Comparing Figs. S9-S10 with Figs. S11-S12, we can see that the finite-frequency and ray tomography methods have generated nearly the same velocity images. The only difference is that the finite-frequency results exhibit slightly higher amplitudes of velocity perturbations, which was also found by the previous studies (e.g., Gautier et al., 2008; Tong et al., 2011). The consistency of the tomographic results generated by the two
different methods is quantitatively verified by the SSIM indices between the two
tomographic models at different depths (Table S2).

Figs. S13 and S14 display the cross-sectional views of tomographic images along
different profiles with the ray tomography method. The corresponding finite-frequency
images are shown in Figs. 3 and 4. Similar to the map views (Figs. 9-12), the overall
patterns of the cross-sectional views generated by the finite-frequency and ray
tomography methods are nearly the same.

Table S1: Structural similarity (SSIM) indices between the checkerboard model and the inversion result at different depths for P-wave and S-wave velocity structures. In the crust (at the depths of 6.0, 12.0, 20.0 and 30.0 km), the SSIM indices are calculated in the Iwaki earthquake and Fukushima nuclear power plant area; while in the upper mantle (at the depths of 40.0, 60.0, 90.0 and 120.0 km), they are calculated for the whole study region. The inversion results are obtained by using finite-frequency tomography (FFT) or ray approach.

Figure S1. Finite-frequency results of a checkerboard resolution test for Vp structure at four representative depth layers in the crust under the Iwaki earthquake and the Fukushima nuclear power plant area.
Figure S2. The same as Fig. S1 but for Vs structure.
Figure S3. Finite-frequency results of a checkerboard resolution test for Vp structure at four representative depth layers in the upper mantle under the whole study area.
Figure S4. The same as Fig. S3 but for Vs structure.
Figure S5. Ray approach results of a checkerboard resolution test for Vp structure at four representative depth layers in the crust under the Iwaki earthquake and the Fukushima nuclear power plant area.
Figure S6. The same as Fig. S5 but for Vs structure.
Figure S7. Ray approach results of a checkerboard resolution test for Vp structure at four representative depth layers in the upper mantle under the whole study area.
Figure S8. The same as Fig. S7 but for Vs structure.
Figure S9. Map views of the P-wave tomography with the ray approach in the crust under the Iwaki earthquake and Fukushima nuclear power plant area. The layer depth is shown below each map. Red and blue colors denote low and high velocities, respectively. The velocity perturbation (in %) scale is shown at the bottom. The brown lines denote the active faults.
Figure S10. The same as Fig. S9 but for Vs structure.
Figure S11. Vertical cross-sections of P-wave velocity, S-wave velocity, and Poisson’s ratio images obtained with the ray tomography along the lines AB (a-c), CD (d-f) and EF.
as shown on the inset map. The vertical exaggeration is 1:1. Small white dots denote the events during 11 March 2011 to 27 October 2011, which are located within 8-km width along each line. The star symbol denotes the hypocenter of the Iwaki mainshock (M 7.0) with a focal depth of 6.4 km, while the open circles show the Iwaki aftershocks (M > 5.0). The square symbol represents the Fukushima nuclear power plant. The Conrad and the Moho discontinuities are shown in dashed lines. This figure is the same as Fig. 3 but obtained with ray tomography.
Figure S12. Vertical cross-sections of (a, b) P-wave and (c, d) S-wave velocity images in the depth range of 0-150 km along the lines AB and CD as shown on the inset map. The vertical exaggeration is 1:1. Small white dots denote the events during 3 June 2002 to 27 October 2011, which are located within a 20-km width along each line. The star and square symbols denote the hypocenter of the Iwaki mainshock (M 7.0) and the
The triangle symbol represents the active volcanoes. The three dashed lines denote the Conrad and Moho discontinuities and the upper boundary of the subducting Pacific slab. This figure is the same as Fig. 4 but obtained with ray tomography.
Figure S13. Examples of the finite-frequency traveltime sensitivity kernels with a dominant frequency of 4.0 Hz in a 1-D velocity model for (a) P-wave and (b) S-wave. The earthquake represented by the star is located within the subducted Pacific slab. The inverse triangle denotes the source and receiver. The curved white lines represent the geometrical ray paths. The yellow lines show the Conrad and Moho discontinuities and the upper boundary of the subducted Pacific slab.
