

Revisionnotes

“The effects of tillage methods on soil aggregation and crop yields in a wheat-corn rotation under semi-arid conditions” submitted by Hossein tabiehzad¹, Gokhan Cayci², Kiarash Afshar Pour Rezaeieh^{3*} (MS No.: se-2017-13)

1) Comments from Anonymous Referee 1

Received and published: 28 March 2017

General comment:

The authors present a study about the influence of tillage methods on soil physical properties and crop yields in a wheat corn rotation in Iran which goes to subjects the journals publications scope. The paper is interesting, but it is not performed to be well understood. The paper have some interest in given subject, but shows several weaknesses which should be changed and discussed. Therefore I suggest reject &re-submission grade in order to improve quality.

Mayor points: The paper is “wordy”, but on the other hand not focused in important findings (e.g. authors do not connect the yields and biomass with physical soils state at each treatment, neither explain their results). The reader gets lost in all the words.

Condense the manuscript. Remove all unnecessary statements and data. Please, avoid repetition and make sure that all statements are credible. The English is not understandable in many places. Also, there is lack of hypothesis in this study and novelty of the study can be explained. Effects of tillage management on plant, soil and environment certainly increase knowledge of how to build more sustainable agricultural systems in Iran. Nevertheless, this subject is extensively studied around the Earth so I wonder how attractive is this subject on international level? The main problem with the paper is that the authors did not provide description of treatments, tool that was used and depth of interventions. This makes the manuscript impossible to evaluate. Introduction section should be rewritten, while recent literature should be used to describe the actual problems. Paper can be better organised – I add some suggestions into text. Furthermore, your data deserves better discussion. Discussion is poor and does not explain neither supports the study results. The authors should say why they have it and not present only the results of the others. More details about sampling procedure are needed.

Specific comments:

Abstract should be rewritten. Please rewrite according next guidelines: Include more information to encourage readers to continue. Many only read title and Abstract. State where you perform the research. State objectives of research, and show whether data meet objectives. State hypotheses tested, and show whether data support hypotheses. Include international classification of soils. Include more data to support statements, and give better summary of the manuscript. Line 14: define “two-course” Line 15: Define “some aggregation properties”? Is better to use “physical properties” or state each property. Line 16: delete “crop” Line 19: Is better to show the results in tonnes per ha. Please change in whole manuscript. Line 21-22. Unclear, please rewrite. Line 24-28. It is hardly understandable. Please ensure English improvement and editing from English speaker. Introduction Please organize the introduction of the paper better. 1: General aspects of tillage impacts on the agro-ecosystems 2: Background about tillage impacts on soil properties that you are studying in this paper. 3: Impacts of tillage and implications trough soil properties (that you study) on crops that you study (generally and in similar agro-ecological conditions). 4: Justify why your study is needed and the novelty of your work. 5: Hypothesis that you want to test in your work and aim. Line 38: write “agricultural” instead “production” Line 39: write “Soil and water conservation are important: :” Line 43: Please, use one term, not many of them – e.g. soil organic carbon – soil organic matter Line 46-48: There is plenty of research availableto support this statement. Add newer literature. Line 49-50: Avoid repetitions Line 50-51: add “distribution” below “rainfall” and “rainfall events”

after “intensity” Line 52: Please avoid generally writing. State which soil characteristics. Line 53-55. Statement is not true. It is not difficult to make intervention (subsoiling) but is expensive. Line 67: unify terms: zero tillage – no tillage – direct sowing. Line 67-69: State in which method? Line 71: Cultivation is tillage. Please delete “cultivation” Line 73-76: Avoid general statements. Instead is better to specify which parameter will be changed and how in short and long term. Support each mentioned parameter with literature source. Line 87: State the difference between excessive tillage and conventional tillage Line 88: write “conservation” instead “protected or reduced” End of introduction: state hypothesis and explain novelty. Introduction: Study that deals with comparison of subsoiling (ripping) with conventional tillage is missing and their effect on soil physical properties and yield.

Materials and Methods Better explanation of experimental design is needed. State the area of each treatment. State the area of sub-treatment. Explanation and description of tillage procedures, tools and depth of tillage is missing. Essential for paper. Line 102: Urumia or Urmia? Line 105: use “terrain” instead “field”. Delete “with very low slope” Table 1: use mg/kg instead ppm Table 2: Check the temperature in June. Remove the comma in May Line 121: which year? Line 122: which year? Soil analyses: Sampling strategy is poorly written. How many disturbed samples per plot were collected? How many undisturbed samples per plot were collected? Same for subplots. How many disturbed and undisturbed samples in total? For undisturbed samples: from which depth? Or depths? Determination procedure for aggregate stability needs some more details: : :
Statistical analysis should be described well.

Results and discussion: This section need to be reordered: 1) bulk density, air filled porosity and hydraulic conductivity, 2) MWD and WSA, 3) field capacity and wilting point, 4) biomass and grain yields. Try to present results in order presented in tables and figures. Highlight most important finding, and state the significant differences between treatments rather than present relative numbers. Discussion is poorly written and does not support, neither explain given differences between treatments. Line 158 and 163: it is not true. Line 165: Deep tillage means nothing. Provide specific information about tillage operation. Line 165-166: compared to what treatment? Line 168: This statement is not supported with results Table 3: state moisture content in grain and biomass. Does numbers represent average of all four seasons? Provide main plot x subplot interaction. Same for each year. Line 173-196: Suggest to authors try to explain their results rather than report other findings. Find and compare your results with study results performed on similar textured soils and climatic conditions. Figures: remove horizontal lines. Unify x –axis and put white background. Table 4: unify digits, remove blank under “molboard” row Line 245: use g per cm³ not gr per cm³. Please make adjustment in whole manuscript. Table 5: change letters in bulk density Line 253: put space after 10 Line 257: Use term “vehicular” instead “farm” Line 258: define “fluffy” Line 258-260: please delete. Does not refers to present subject Line 261: define “effective pore” Line 263 and 265: put % behind numbers Line 293-296: Does this study deals with crop rotation effect? Please delete this Line 297-299: What is procedure with residues in this experiment? Add this information in M&M section Line 301-303: When you compare results with others please provide information about tool that were used and depth of intervention instead using terms “reduced” and “minimum”. Otherwise is meaningless comparison.

Conclusions Line 349-350: Authors presents only single factor effect. If you want a draw a conclusion similar to written than you should test an interaction effect. This statement is not confirmed. Line 351-353: did you study subsoil layers also? Or just topsoil? Please delete this, it is not investigated. Make conclusions from your results. Line 366-369: Effect of subsoiling on silty clay soils do not last longer than season or two. Please adjust conclusion like: : : .. “subsoiling is suggested in years when crops with demands for deeper rooting occurs in crop rotation.”
Literature There are only two (2) sources in last 5 years. I suggest refreshing the paper with newer literature.

2) Author’s Response and Changesin manuscript for referee I

General Comment

First of all, we thank to the referee to review the manuscript in a short time and read carefully. We are grateful for referee for sharing experience and knowledge with us. Referee critics are constructive and guiding for authors.

We would like to mention that authors attempted to remove unnecessary parts as much as possible and tried to make the article more readable in the direction of referee suggestions.

In this context;

Unnecessary repetitions were avoided.

Our hypotheses and novelty of the study was explained.

Detailed sampling procedure was explained.

Treatments related to soil tillage practices were explained in detail.

The relations between crop yields and soil properties were tried to be explained in more detail.

The article was tried better to organize by considering the referee critics.

Some parts of the manuscript were re-written and re-configured with referee suggestions. In this context, some explanations and references not directly related to the subject were removed and new explanations and references were added to new version.

Specific comments

Our answers to the critics and suggestions for each section of the article are presented below.

Abstract

This section was completely re-organized with referee suggestions.

“two-course” line 15 was deleted.

“crop” line 16 was deleted

“kg/ha” unit corrected as tonnes/ha (It was done in whole article)

Line 21-22 was rewritten as “Subsoiler+rotary tiller treatment gave the highest mean weight diameter (MWD) with a value of 2,063mm($P<0.05$)”.

Line 24-28 were rewritten as “When sub-plot means were considered bulk density was the highest in disc harrow treatment with a value of 1.39 gcm^{-3} ($P<0.05$), total porosity and air porosity values were significant at ($P<0.01$) and the highest values were as 51.20% and 12.05% in rotary tiller application, respectively”.

Introduction

Line 38 production changed as “agricultural”

Line 39 was corrected as “soil and water conservation”

Line 46-48 “Anonymous” was deleted a new literature (Kasper et al. 2009) was added.

Line 49-50 was deleted because of previous repetition.

Line 50-51 sentence was corrected as “Due to irregularities in distribution of rainfall with regard to time and intensity of rainfall events in arid and semi-arid regions”

Line 52 was corrected as “Moreover, excessive or incorrect tillage reduce aggregate wettability and decrease soil organic pool” and reference “Marinari et al. 2000” was removed.

Line 67 “direct sowing” was deleted.

Line 65-67 was changed as 15 up to 30 percent of plant residues remain on the surface part of the soil at “conservation tillage” system

Line 71 “cultivation” was deleted.

Line 87 “excess tillage” was removed.

Hypothesis and novelty of the study were added end of introduction section.

Materials and methods

An explanation about treatment in relation to plot design was added to the 2.2.1 section as “Parcel sizes and space between blocks, main plots and sub-plots were given.

“Tillage depths were presented”

Soil sampling was explained in detail in a separate sub section as “soil collection” in material and method section as 2.2.2.

Explanation about sampling before version was moved 2.2.2 section and sampling method was rewritten. An explanation for undistributed soil sampling was added to the 2.2.2 section

Line 102 was corrected as “Urmia”.

Line 105 “with very low slope” was removed.

Table 1 “ppm” unit was changed as “mg/kg”

Temperature in June was corrected as “11.8” in Table 2.

Line 121 “comma in May was removed”

Line 121-122 experiment Trial years were specified.

Section 2.2.3 was re-written in detail in terms of statistical analyses.

Results and discussion

Results and discussion section was re-configured according to referee suggestion. In this context below mentioned sections constituted in results and discussion part

3.1 Grain and biomass yield of wheat and corn

3.2 Mean weight diameter of aggregates and water stable aggregates

3.3 Bulk density, air filled porosity and total porosity and hydraulic conductivity

3.4 Field capacity and wilting point

Line 158-163 placement error in Table 3 related to tillage methods was corrected.

Line 165-166 was corrected as “Arora (1991), reported that 30cm deep chiselling was positively effective reducing water stress in corn. On the other hand, Gajri et al. (1997) reported that sub-soiling with a single tine chisel down to 0.40 m depth practices in semi-arid regions of India has been proved to be effective in utilization of water in sunflower production in semi-arid regions compared with conventional tillage.” and these explanation transferred to a further segment in the same section.

Numbers in Table 3 represent average of all seasons.

Stated grain and biomass amounts were determined after harvesting for each year. Moisture contents in grain and biomass were not measured.

Horizontal lines in figures were removed and inserted white background. Blanks in Table 4 was corrected.

Line 245 and Table 5 “gr cm⁻³” units were changed as “gcm⁻³” it was done also in whole manuscript.

Line 257 “vehicular” term was used instead of “farm”.

Line 258-260 was deleted and reference was removed from reference list.

Line 261-261 was deleted reference was removed from reference list.

Line 265 “%” was put behind numbers.

Line 297-299 was deleted reference was removed from reference list.

Conclusion

Line 349-350 was rewritten according to referee’s critics.

Line 351-354 was deleted.

Line 366-369 was rewritten according to referee’s suggestions.

Literature

Newer references were added to the manuscript as much as possible
